- Amortized complexity analysis
- Iterator

Today

- Linked Lists
 - Singly linked lists
 - Doubly linked lists
 - Iterator for linked lists

Dynamic Array - review

The elements of a dynamic array occupy a contiguous memory block.

Advantages:

- accessing any element in Θ(1)
- adding at the end in $\Theta(1)$ amortized and removing from the end in $\Theta(1)$ (amortized)
- Disadvantages:
 - adding and removing from the beginning of the array in $\Theta(n)$

Linked Lists

A linked list is a linear data structure consisting of nodes, the order of the elements being determined not by indexes, but by pointers stored in each node.

Each node contains, besides the data, a pointer to the next node (and possibly a pointer to the previous node).

Linked Lists

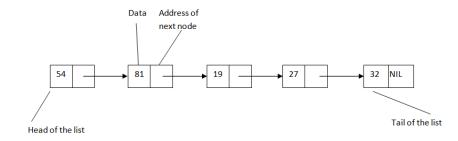

The nodes of a linked list are not necessarily adjacent in memory. This is why we need to keep a pointer to the next node in each node.

We can directly access only the first node (and maybe the last one) of the list. For the other nodes and, therefore, elements, the access is sequential.

Linked Lists

E Example of a linked list with 5 nodes:

This is actually a **singly** linked list (SLL).

Singly Linked Lists - SLL

Each SLL node contains the data and the pointer to the next node.

The first node of the list is called the **head** of the list and the last node is called the **tail** of the list.

The tail of the list contains the special value *NIL* as the pointer to the next node (which does not exist).

If the head of the linked list is NIL, then the list is empty.

Singly Linked Lists - Representation

 To represent a SLL we need two structures: one for the node and one for the list itself.

SLL's node representation:

SLLNode:

info: TElem //the actual information

next: ↑ SLLNode //pointer to the next node

SLL representation:

SLL:

head: ↑ SLLNode //address of the first node

Usually, for a SLL, we only memorize the pointer to the head.

SLL - Operations

Possible operations for a singly linked list:

- searching for an element with a given value
- adding an element (at the beginning, to the end, at a given position)
- deleting an element (from the beginning, from the end, from a given position, with a given value)
- getting the element from a given position

These are *possible* operations; usually we need only part of them (depending on the container that we implement).

SLL - Search

Searching a given element into a SLL:

function search (sll, elem) is:

//pre: sll is a SLL; elem is a TElem

//post: returns a pointer to a node which contains elem as info,

//or NIL if sll does not contain the given element

SLL - Search

Searching a given element into a SLL:

```
function search (sll, elem) is:
//pre: sll is a SLL; elem is a TElem
//post: returns a pointer to a node which contains elem as info,
//or NIL if sll does not contain the given element
    current ← sll.head
    while current ≠ NIL and [current].info ≠ elem execute
        current ← [current].next
    end-while
    search ← current
end-function
```

What is the time complexity?

SLL - Search

Searching a given element into a SLL:

```
function search (sll, elem) is:
//pre: sll is a SLL; elem is a TElem
//post: returns a pointer to a node which contains elem as info,
//or NIL if sll does not contain the given element
    current ← sll.head
    while current ≠ NIL and [current].info ≠ elem execute
        current ← [current].next
    end-while
    search ← current
end-function
```

What is the time complexity?

Inserting at the beginning of a SLL:

subalgorithm insertFirst (sll, elem) is:

//pre: sll is a SLL; elem is a TElem

//post: elem will be inserted at the beginning of sll

Inserting at the beginning of a SLL:

 $\textbf{subalgorithm} \ insertFirst \ (sll, \ elem) \ \textbf{is:}$

//pre: sll is a SLL; elem is a TElem

//post: elem will be inserted at the beginning of sll

newNode ← allocate() //allocate a new SLLNode

 $[newNode].info \leftarrow elem$

 $[newNode].next \leftarrow sll.head$

sll.head ← newNode

end-subalgorithm

What is the time complexity?

Inserting at the beginning of a SLL:

subalgorithm insertFirst (sll, elem) is:

//pre: sll is a SLL; elem is a TElem

//post: elem will be inserted at the beginning of sll

newNode ← allocate() //allocate a new SLLNode

 $[newNode].info \leftarrow elem$

[newNode].next \leftarrow sll.head

sll.head ← newNode

end-subalgorithm

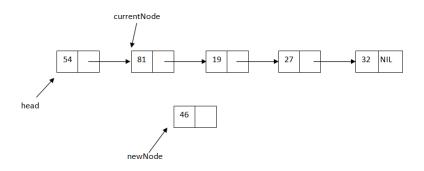

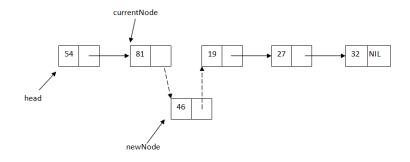

What is the time complexity?

 $\Theta(1)$

Suppose that we have the pointer to a node from a SLL and we want to insert a new element after that node.

Inserting after a node in a SLL:

```
subalgorithm insertAfter(sll, currentNode, elem) is:

//pre: sll is a SLL; currentNode is an SLLNode from sll;

//elem is a TElem

//post: a node with elem will be inserted after node currentNode

newNode ← allocate() //allocate a new SLLNode

[newNode].info ← elem

[newNode].next ← [currentNode].next

[currentNode].next ← newNode

end-subalgorithm
```

What is the time complexity?

Inserting after a node in a SLL:

subalgorithm insertAfter(sll, currentNode, elem) is:
//pre: sll is a SLL; currentNode is an SLLNode from sll;
//elem is a TElem
//post: a node with elem will be inserted after node currentNode
newNode ← allocate() //allocate a new SLLNode
[newNode].info ← elem
[newNode].next ← [currentNode].next
[currentNode].next ← newNode
end-subalgorithm

What is the time complexity?

Insert before a node

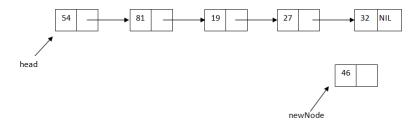

How can we insert an element to a given integer position in a SLL?

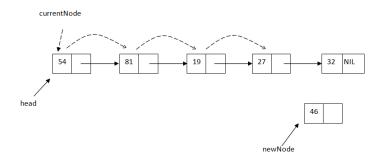

How can we insert an element to a given integer position in a SLL?

We first need to find the node at the position *after* which we need to insert the element.

Assume that we want to insert 46 at position 5.

We need the 4th node (to insert the new node after it), but we have no direct access to it. So we have to traverse the list to it using and auxiliary pointer (*currentNode*).

Now, we insert the new node after the node pointed by currentNode

Inserting at a given position into a SLL:

```
subalgorithm insertPosition(sll, pos, elem) is:
//pre: sll is a SLL; pos is an integer number; elem is a TElem
//post: a node with TElem will be inserted at position pos in sll
   if pos < 1 then
      @error, invalid position
   else if pos = 1 then //we want to insert at the beginning
      newNode ← allocate() //allocate a new SLLNode
      [newNode].info \leftarrow elem
      [newNode].next ←sll.head
      sll.head ← newNode
   else
      currentNode ← sll.head
      currentPos ← 1
      while currentPos < pos - 1 and currentNode ≠ NIL execute
         currentNode \leftarrow [currentNode].next
         currentPos ← currentPos + 1
      end-while
//continued on the next slide...
```

Inserting at a given position into a SLL:

```
if currentNode \neq NIL then
       newNode ← allocate() //allocate a new SLLNode
       [newNode].info \leftarrow elem
       [newNode].next ← [currentNode].next
       [currentNode].next \leftarrow newNode
     else
       @error, invalid position
     end-if
  end-if
end-subalgorithm
```

What is the time complexity?

Inserting at a given position into a SLL:

```
if currentNode \neq NIL then
       newNode ← allocate() //allocate a new SLLNode
       [newNode].info \leftarrow elem
       [newNode].next ← [currentNode].next
       [currentNode].next \leftarrow newNode
     else
       @error, invalid position
     end-if
  end-if
end-subalgorithm
```

What is the time complexity?

O(r

Get element from a given position

How can we access an element at a position p from a SLL?

Get element from a given position

How can we access an element at a position *p* from a SLL?

Since we only have direct access to the head of the list, we have to go through the list, node-by-node, until we get to the p^{th} node.

The process is similar to the first part of the *insertPosition* subalgorithm.

SLL - Obtain the element at a given position

Containing the element at a given position in a SLL:

```
function getElement(sll, pos) is:
//pre: sll is a SLL; pos is an integer number
//post: getElement is a TElem representing the element at position pos in sll
   if pos < 1 then
      @error, invalid position
   else:
      currentNode ← sll.head
      currentPos ← 1
      while currentPos < pos and currentNode \neq NIL execute
         currentNode \leftarrow [currentNode].next
         currentPos ← currentPos + 1
      end-while
      if currentNode ≠ NIL then
         getElement ← [currentNode].info
      else:
         @error, invalid position
      end-if
   end-if
end-function
```

SLL - Delete a given element

How can we delete an element from a SLL given either by its value or its position?

SLL - Delete a given element

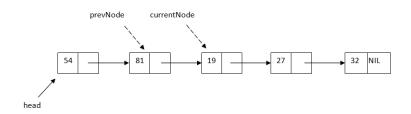

How can we delete an element from a SLL given either by its value or its position?

We need to find the node *before* the one we want to delete. We can do this by walking through the list using two pointers, *currentNode* and *prevNode* (pointing to the previous node), until *currentNode* points to the node to be deleted.

E Suppose we want to delete the node with information 19.

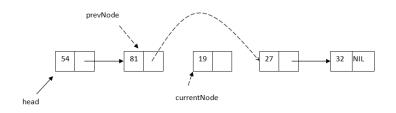

Traverse the list with the two pointers until *currentNode* points to the node we want to delete.

Delete the node pointed by *currentNode* by *jumping over it*.

Deleting a given element from a SLL:

function deleteElement(sll, elem) is:

//pre: sll is a SLL, elem is a TElem

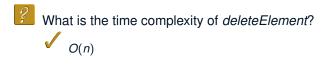

//post: the node with elem is removed from sll and returned

Deleting a given element from a SLL:

```
function deleteElement(sll, elem) is:
//pre: sll is a SLL, elem is a TElem
//post: the node with elem is removed from sll and returned
  currentNode ← sll.head
   prevNode ← NIL
  while currentNode \neq NIL and [currentNode].info \neq elem execute
      prevNode ← currentNode
      currentNode ← [currentNode].next
  end-while
   if currentNode ≠ NIL AND prevNode = NIL then //we delete the head
      sll.head \leftarrow [sll.head].next
  else if currentNode ≠ NIL then
      [prevNode].next ← [currentNode].next
  end-if
  deleteElement ← currentNode
end-function
```

SLL - Iterator

How can we define an iterator for a SLL? What would be the type of the iterator's cursor?

SLL - Iterator

How can we define an iterator for a SLL? What would be the type of the iterator's cursor?

The iterator's cursor is a pointer to the current node in the list.

SLL - Iterator

SLL Iterator's representation:

SLLIterator:

list: SLL

currentElement: ↑ SLLNode

SLL - Iterator - init operation

The constructor of an iterator over a SLL:

subalgorithm init(i, sll) is:

//pre: sll is a SLL

//post: i is a SLLIterator over sll

 $i.sll \leftarrow sll$

i.currentElement \leftarrow sll.head

end-subalgorithm

SLL - Iterator - init operation

The constructor of an iterator over a SLL:

subalgorithm init(i, sll) is:

//pre: sll is a SLL

//post: i is a SLLIterator over sll

 $i.sll \leftarrow sll$

i.currentElement ← sll.head

end-subalgorithm

What is the time complexity?

 $\Theta(1)$

SLL - Iterator - getCurrent operation

Returning the current element referred by a SLL Iterator:

```
function getCurrent(i) is:
//pre: i is a SLLIterator, i is valid
//post: getCurrent ← e, e is TElem, the current element referred by i
//throws: exception if i is not valid
if i.currentElement = NIL then
@throw an exception
end-if
getCurrent ← [i.currentElement].info
end-function
```

SLL - Iterator - getCurrent operation

Returning the current element referred by a SLL Iterator:

```
function getCurrent(i) is:
//pre: i is a SLLIterator, i is valid
//post: getCurrent ← e, e is TElem, the current element referred by i
//throws: exception if i is not valid
    if i.currentElement = NIL then
       @throw an exception
    end-if
    getCurrent ← [i.currentElement].info
end-function
```

SLL - Iterator - next operation

The next operation for a SLL Iterator:

subalgorithm next(i) is:

//pre: i is a SLLIterator, i is valid

//post: i' is a SLLIterator, the cursor of i' refers to the next element

//throws: exception if i is not valid

if i.currentElement = NIL then

@throw an exception

end-if

 $i.currentElement \leftarrow [i.currentElement].next$

end-subalgorithm

SLL - Iterator - next operation

The next operation for a SLL Iterator:

subalgorithm next(i) is:

//pre: i is a SLLIterator, i is valid

//post: i' is a SLLIterator, the cursor of i' refers to the next element

//throws: exception if i is not valid

if i.currentElement = NIL then

@throw an exception

end-if

 $i.currentElement \leftarrow [i.currentElement].next$

end-subalgorithm

What is the time complexity?

 $\Theta(1)$

SLL - Iterator - valid operation

The valid function of a SLL Iterator:

```
function valid(it) is:
//pre: it is a SLLIterator
//post: true if it is valid, false otherwise
if it.currentElement ≠ NIL then
valid ← True
else
valid ← False
end-if
end-subalgorithm
```

SLL - Iterator - valid operation

The valid function of a SLL Iterator:

```
function valid(it) is:
//pre: it is a SLLIterator
//post: true if it is valid, false otherwise
if it.currentElement ≠ NIL then
valid ← True
else
valid ← False
end-if
end-subalgorithm
```

Think about it

How could we define a bi-directional iterator for a SLL? What would be the complexity of the *previous* operation?

How could we define a bi-directional iterator for a SLL if we know that the *previous* operation will never be called twice consecutively (two consecutive calls for the *previous* operation will always be divided by at least one call to the *next* operation)? What would be the complexity of the operations?

Doubly Linked Lists - DLL

A **doubly linked list** is a linked list in which each node not only contains a pointer to the next node, but also a pointer to the previous one.

The first node has *NIL* as the pointer to the previous node (just like the last element has NIL as the pointer to the next node).

Singly vs. doubly linked list

- There are trade-offs when choosing between SLL and DLL:
 - SLL uses less memory, but we don's have direct access to the previous elements.
 - DLL can be easily traversed backwards, but it uses more memory.

Example of a Doubly Linked List

Example of a **doubly linked list** with 5 nodes:

Doubly Linked List - Representation

 To represent a DLL we need two structures: on for the node and one for the list itself.

A DLL's node representation:

DLLNode:

info: TElem

next: ↑ DLLNode prev: ↑ DLLNode

Representation of a DLL:

DLL:

head: ↑ DLLNode tail: ↑ DLLNode

DLL - Creating an empty list

- An empty list is one which has no nodes ⇒ the address of the first node (and the address of the last node) is NIL
 - When we add or remove or search, we know that the list is empty if its head is NIL.

subalgorithm init(dll) is:

//pre: true //post: dll is a DLL dll.head ← NIL

 $dII.tail \leftarrow NIL$

end-subalgorithm

DLL - Creating an empty list

- An empty list is one which has no nodes ⇒ the address of the first node (and the address of the last node) is NIL
 - When we add or remove or search, we know that the list is empty if its head is NIL.

Creating an empty DLL:

subalgorithm init(dll) is:

//pre: true

//post: dll is a DLL

 $dll.head \leftarrow NIL$

 $dll.tail \leftarrow NIL$

end-subalgorithm

DLL - Operations

Possible operations for a doubly linked list:

- searching for a given element
- adding an element (at the beginning, to the end, at a given position)
- deleting an element (from the beginning, from the end, from a given position, with a given value)
- getting the element from a given position

Some of the operations have the exact same implementation as for a SLL (e.g. *search*, *getElement*), but in general we need to modify more links and to pay attention to the *tail*.

DLL - Adding at the end

Adding a new element to the end of a DLL is simple. Because we have the *tail* of the list, we do not have to walk through all the elements (like we have to do in case of a SLL).

Adding an element at the end of a DLL:

```
subalgorithm insertLast(dll, elem) is:
//pre: dll is a DLL, elem is TElem
//post: elem is added to the end of dll
   newNode ← allocate() //allocate a new DLLNode
   [newNode].info \leftarrow elem
   [newNode].next \leftarrow NIL
   [newNode].prev ← dll.tail
   if dll.head = NIL then //the list is empty
      dll.head ← newNode
   else
      [dll.tail].next ← newNode
   end-if
   dll.tail ← newNode
end-subalgorithm
```

Adding an element at the end of a DLL:

```
subalgorithm insertLast(dll, elem) is:
//pre: dll is a DLL, elem is TElem
//post: elem is added to the end of dll
   newNode ← allocate() //allocate a new DLLNode
   [newNode].info ← elem
   [newNode].next \leftarrow NIL
   [newNode].prev ← dll.tail
   if dll.head = NIL then //the list is empty
      dll.head ← newNode
   else
      [dll.tail].next ← newNode
   end-if
   dll.tail ← newNode
end-subalgorithm
```

DLL - Insert at a given position

How can we insert an element to a given integer position into a DLL?

DLL - Insert at a given position

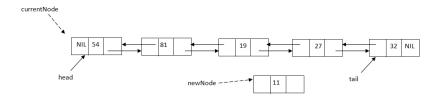

How can we insert an element to a given integer position into a DLL?

The principle is the same as in the case of a SLL excepting that:

★ We need to also (re)set links to previous node
 ★ We may need to reset the tail of the list
 ✓ We can stop either before of after the position we want to insert the element at

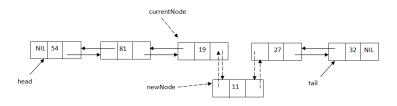

DLL - Insert on position

 \blacksquare Let's insert value 11 at the 4th position in the following list:

DLL - Insert on position

We move with the *currentNode* to position 3, and set the 4 links.

DLL - Insert at a position

Inserting at a given position into a DLL:

```
subalgorithm insertPosition(dll, pos, elem) is:
//pre: dll is a DLL; pos is an integer number; elem is a TElem
//post: elem will be inserted on position pos in dll
   if pos < 1 then
      @ error, invalid position
   else if pos = 1 then
      insertFirst(dll, elem)
   else
      currentNode ← dll.head
      currentPos ← 1
      while currentNode ≠ NIL and currentPos < pos - 1 execute
         currentNode \leftarrow [currentNode].next
         currentPos ← currentPos + 1
      end-while
//continued on the next slide...
```

DLL - Insert at position

Inserting at a given position into a DLL:

```
if currentNode = NII then
          @error, invalid position
      else if currentNode = dlLtail then
          insertLast(dll, elem)
      else
          newNode ← allocate()
          [newNode].info \leftarrow elem
          [newNode].next \leftarrow [currentNode].next
          [newNode].prev \leftarrow currentNode
          [[currentNode].next].prev \leftarrow newNode
          [currentNode].next \leftarrow newNode
      end-if
   end-if
end-subalgorithm
```

DLL - Insert at position

Inserting at a given position into a DLL:

```
if currentNode = NII then
          @error, invalid position
      else if currentNode = dlLtail then
          insertLast(dll, elem)
      else
          newNode ← allocate()
          [newNode].info \leftarrow elem
          [newNode].next \leftarrow [currentNode].next
          [newNode].prev \leftarrow currentNode
          [[currentNode].next].prev \leftarrow newNode
          [currentNode].next \leftarrow newNode
      end-if
   end-if
end-subalgorithm
```

DLL - Delete a given element

If we want to delete a given element, we first have to find the node containing it.

- Special cases:
 - the element is not in list (includes the case of an empty list)
 - remove head (which may be tail as well)
 - remove tail

Deleting a given element:

```
function deleteElement(dll, elem) is:
//pre: dll is a DLL, elem is a TElem
//post: the node with element elem will be removed and returned
   currentNode ← dll.head
   while currentNode \neq NIL and [currentNode].info \neq elem execute
      currentNode ← [currentNode].next
   end-while
   deletedNode ← currentNode
   if currentNode ≠ NIL then
      if currentNode = dll.head then //remove the first node
         if currentNode = dll.tail then //which is the last one as well
            dll head ← NII
            dlLtail ← NII
         else //list has more than 1 element, remove first
            dll.head ← [dll.head].next
            [dll.head].prev ← NIL
         end-if
//continued on the next slide...
```

DLL - Delete a given element

Deleting a given element:

```
else if currentNode = dll.tail then
        dll.tail \leftarrow [dll.tail].prev
        [dll.tail].next \leftarrow NIL
     else
        [[currentNode].next].prev \leftarrow [currentNode].prev
        [[currentNode].prev].next ← [currentNode].next
        @set links of deletedNode to NIL to separate it from the
nodes of the list
     end-if
  end-if
  deleteElement ← deletedNode
end-function
```

What is the time complexity?

DLL - Delete a given element

Deleting a given element:

```
else if currentNode = dll.tail then
        dll.tail \leftarrow [dll.tail].prev
        [dll.tail].next \leftarrow NIL
     else
        [[currentNode].next].prev ← [currentNode].prev
        [[currentNode].prev].next ← [currentNode].next
        @set links of deletedNode to NIL to separate it from the
nodes of the list
     end-if
  end-if
  deleteElement ← deletedNode
end-function
```

What is the time complexity?

Iterating through all the elements of a linked list

- Similar to the DynamicArray, if we want to go through all the elements of a (singly or doubly) linked list we have two options:
 - Use an iterator
 - Use a for loop and the getElement function
- What is the complexity of the two approaches?

Traversing a SLL with Iterator

Printing all the elements of an SLL using the iterator:

```
subalgorithm printSLLWithIterator(sll) is:

//pre: sll is a SLL
init(i, sll)

while valid(i) execute

//get the current element referred by the iterator
elem ← getCurrent(i)
print elem
//go to the next element
next(i)
end-while
end-subalgorithm
```

What is the complexity of printSLLWithIterator?

Traversing a SLL using getElement

Printing all the elements of a ALL using getElement:

```
 \begin{tabular}{ll} \textbf{subalgorithm} & printSLLUsingGetCurrent(sll) is: \\ \textit{//pre: sll is a SLL} \\ \textbf{for i} \leftarrow 1, & size(sll) & \textbf{execute} \\ & elem \leftarrow & getElement(sll, i) \\ & \textbf{print} & elem \\ & \textbf{end-for} \\ \end{tabular}
```

What is the complexity of printSLLUsingGetCurrent?

Dynamic Array vs. Linked Lists

Advantages of Linked Lists:

- No memory used for non-existing elements
- Constant time complexity for the operations at the beginning
- Elements are never moved / shifted
- Overflow can never occur unless the memory is actually full.
- Disadvantages of Linked Lists:
 - No direct / random access to an element at a given position
 - Extra space is used up by the addresses stored in the nodes

Containers represented using linked lists

Linked lists are used for representing the following containers:

- ADT List
 - LinkedList in Java, forward_list (SLL) and list (DLL) in C++ STL
- ADT Stack
 - Stack in C++
- ADT Queue
 - Queue in C++
- ADT Bag
- ADT Set

Linked lists - Applications

Applications of linked lists:

Compilers

For symbol table management

Web browsers

To keep track of the visited pages

Music player

 A music player can use a linked list to allow switching to the next/previous song

Text editors

Undo and Redo mechanism in Excel, Notepad, WordPad, etc.

Multi-player games

To keep the track of turns
